EXPERIMENT 7

Integrating a Zoho Creator Application with Zoho CRM

Using Connections and Deluge — EcoCycle Collection Request (Lead Creation Use Case)

Jenell S G | Roll Number: 240701212

1. Aim

To integrate the EcoCycle application with Zoho CRM using a microservice connection and Deluge scripting, so that every submitted Collection Request automatically creates a lead in the Zoho CRM Leads module.

Objectives

- To create and authorise a Zoho CRM connection under Microservices.
- To verify that the connection shows the Connected status and is available to the application.
- To write a form workflow on Collection Request that maps requester details to a CRM lead using zoho.crm.createRecord.
- To test the integration by submitting collection requests and checking the Leads module.

2. Procedure

Phase A: Creating the connection

1. Sign in to Zoho Creator and open the Creator home page.
2. In the left panel under **Develop**, click **Microservices** and open the **Connections** tab.
3. Choose **Zoho CRM** from the available services and select **Create And Authorize** using the Zoho credential.
4. Confirm that the connection card shows the type **System** and the status **Connected** (Figure 7.1).

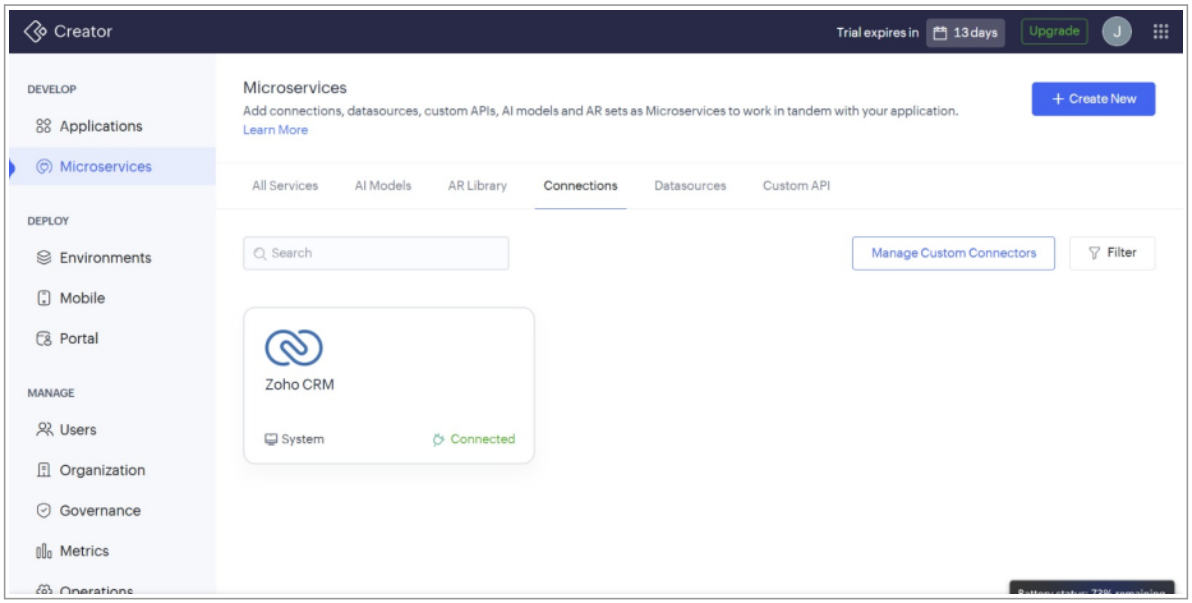

Figure 7.1: Microservices → Connections showing the Zoho CRM connection in the Connected state

Phase B: Verifying the connection in the application

1. Open the live EcoCycle application and select **App Preferences** in the menu.
2. The **Manage Integrations** panel opens on the right and lists **Zoho CRM – Zoho CRM Account** as Connected (Figure 7.2).

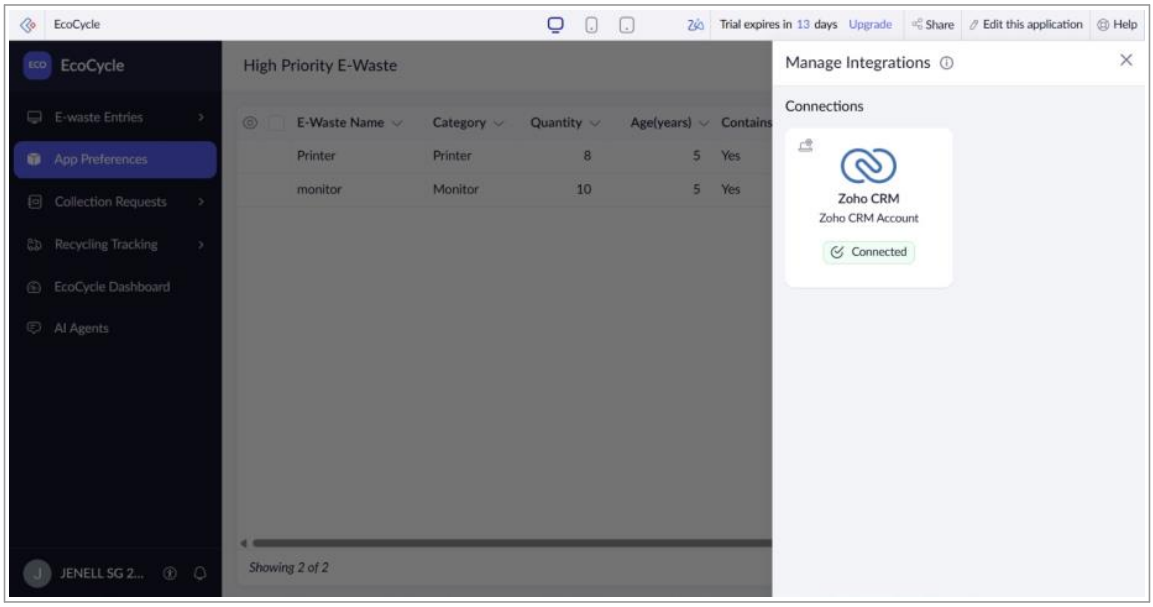

Figure 7.2: Manage Integrations panel (App Preferences) showing Zoho CRM Connected

Phase C: Creating the workflow

1. Open the **Collection Request** form and select **Workflow**.
2. Create a form workflow named **Create CRM Lead** with Record Event **Created** and Form Event **Successful form submission**.
3. Leave the action to run **Always**, so that every request creates a lead.
4. Choose **Deluge script** as the action type.

Collection Request field	Zoho CRM Lead field	Remark
Requester Name	Last_Name (Lead Name)	Lead name equals the requester name
Collection Location	Company	Block name (A block, D block, B block) is stored as the company
Email	Email	Addresses match
Phone Number	Phone	Column cut off in the CRM screenshot

Phase D: Writing the Deluge script

1. Build a map of lead fields from the submitted values.
2. Call **zoho.crm.createRecord** for the Leads module and pass the connection link name.
3. Use **info** to write the response to the log and click **Update** to save.

Listing 7.1: Create a Zoho CRM lead (DS-04)

```
// Form: Collection Request | Event: Created > Successful form submission
// Connection link name used here: zoho_crm_connection (assumed)
leadMap = Map();
leadMap.put("Last_Name", input.Requester_Name);
leadMap.put("Company", input.Collection_Location);
leadMap.put("Email", input.Email);
leadMap.put("Phone", input.Phone_Number);
resp = zoho.crm.createRecord("Leads", leadMap, Map(), "zoho_crm_connection");
info resp;
```

Note: this listing is the reference implementation of the project report (Appendix C.4). Use the link name of your own connection.

Phase E: Testing

1. Open the live **Collection Request** form (Figures 7.3 and 7.4).
2. Submit four requests (monica, swathi, shreya and jenell) with category, quantity, preferred date and time.
3. Open the **Collection Requests** report and then Zoho CRM → Leads.

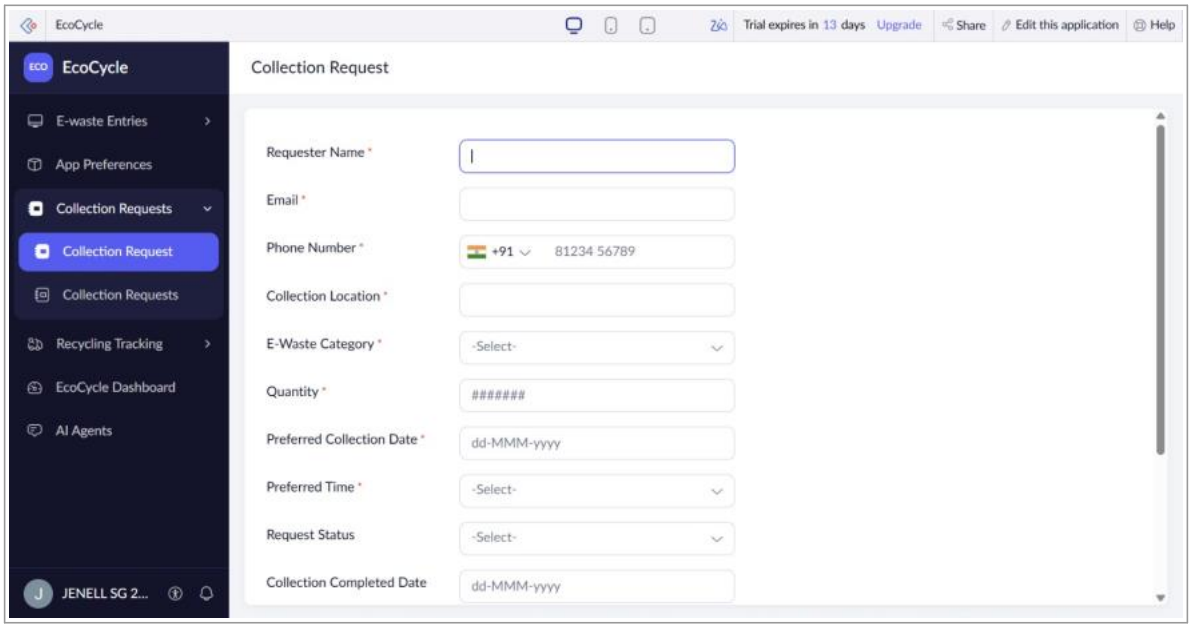

Figure 7.3: Collection Request form (upper part)

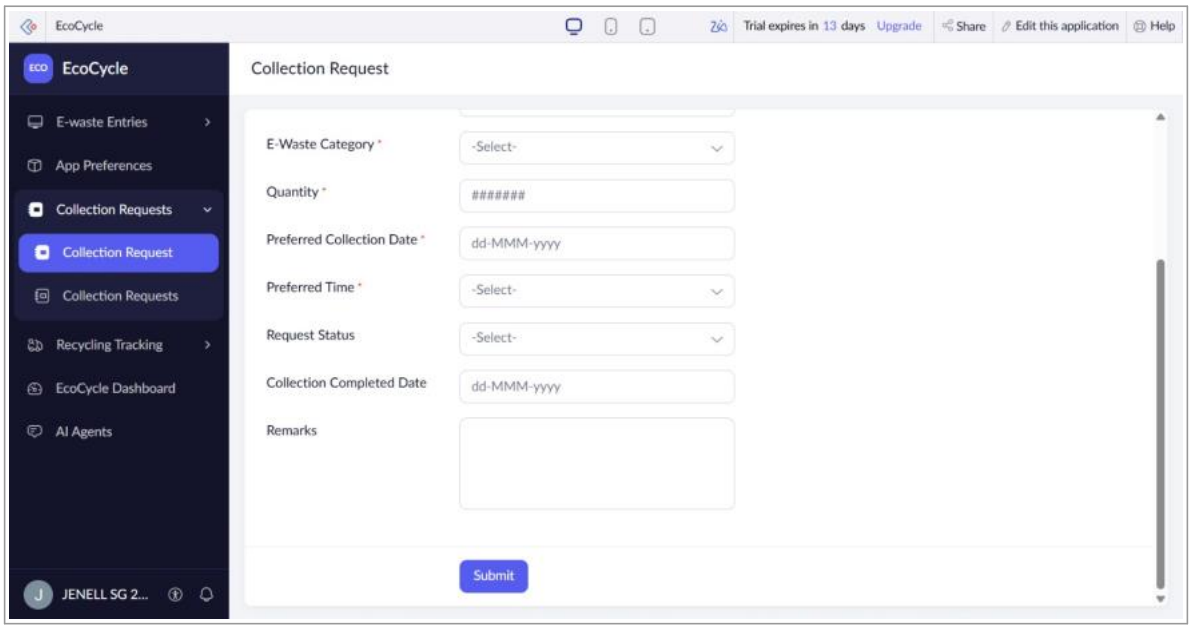

Figure 7.4: Collection Request form (lower part)

3. Output & System Verification

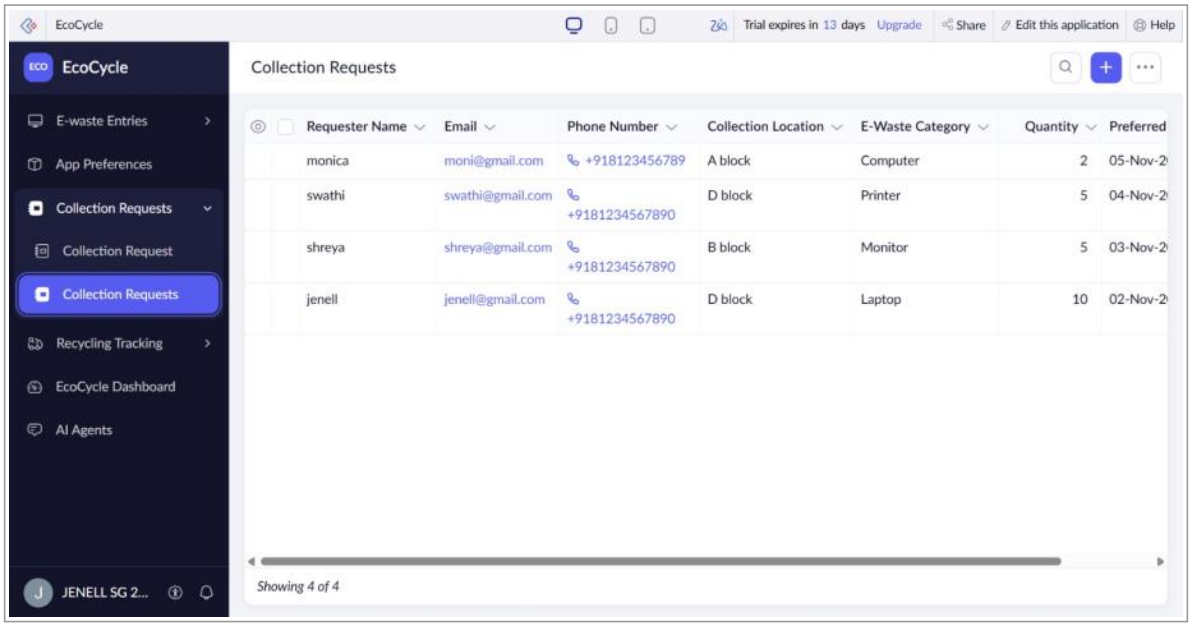

Figure 7.5: Collection Requests report — four requests (Showing 4 of 4)

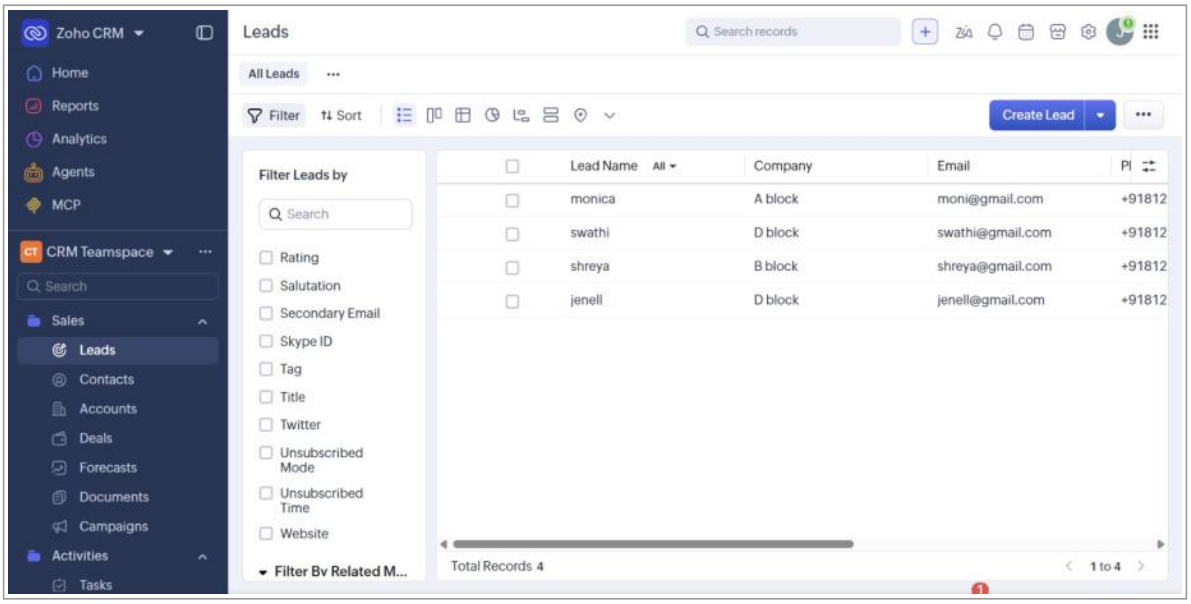

Figure 7.6: Zoho CRM Leads module — four leads created from the collection requests (Total Records: 4)

Requester (Creator)	Location	Lead Name (CRM)	Company (CRM)	Match
monica	A block	monica	A block	Yes
swathi	D block	swathi	D block	Yes
shreya	B block	shreya	B block	Yes
jenell	D block	jenell	D block	Yes

Observations

- The Zoho CRM connection is in the Connected state in Microservices and in the Manage Integrations panel.
- Each of the four collection requests has one lead in Zoho CRM; lead names, e-mail addresses and the company (collection location) match the requests.
- The CRM phone column was cut off in the screenshot, so the phone mapping is not claimed beyond the script design.
- If the connection is revoked, no lead is created; the connection status should be checked under Microservices (planned test TC-18).

4. Result

The EcoCycle application was connected to Zoho CRM through a microservice connection, and a form workflow on Collection Request creates a lead for every submitted request. Four collection requests produced four matching leads in the Zoho CRM Leads module.

5. Conclusion

The experiment shows that a low-code application can exchange data with another Zoho service without any server or token handling in the code: the connection holds the authorisation, and a few lines of Deluge map the form fields to the CRM lead. The connection must stay authorised for the workflow to work, so its status should be reviewed regularly.
